## ABSTRACT

This report presents findings of a national mail survey of school principals conducted by the National Center for Education Statistics (NCES) in Spring 1982 to assess recent changes in computer availability and to obtain data about instructional uses and needs from the school perspective. Results are reported for the following topics addressed by the questionnaire: number of computers available for all uses (instructional and non-instructional) and for instructional use by students in the 1981-1982 school year; number of students using computers for instruction and the number of computer hours of instructional use in the 1981-1982 school year; relative amount of computer time devoted to various instructional purposes; number of teachers trained to teach computer literacy (introduction to computer concepts); number of gredits that students could earn in computer literacy and computer science; need for and sources of microcomputer courseware; instructional software; and needs for initiating or improving computer based education. Appendices include a discussion of the survey methodology and sampling errors and a copy of the survey questionnaire. (LMM)

FRSS Report No. 14

response surveu surveu sustem

2

According to school administrators, to pergent of the Nation's public schools used consignitions (included consignitions) for instruction in the less-sy schools (2. percent) and computers, that were used trictly for nonlinstructional purposes:

The symbolity of complete-based edication whiled by the instructional level of elementary from 22 percent of elementary chooses to 74 percent of senior high chools.

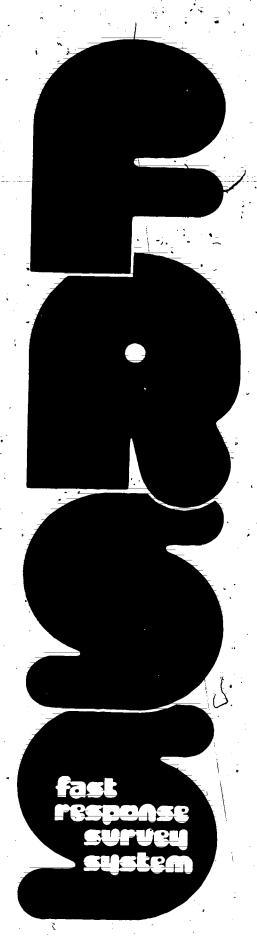

A total of 141,000 computer units were evaluate for instructional use in 1981-82; notwice 1511 (980 and spring 1982, the number of computers used for instruction dentied; improcephiputers, which tripled in number during that period, accounted for most of the ingrease.

According to school administrators, 4.7 addition students (11 percent of the public school computers) find access to computers up instruction in 1981-82. These students everaged 9 hours for computer time for instruction during that year.

Computer usage varied by type of comestator unit and by instructional level. The union application of migrocomputers was for teaching computer literacy (introduction to doubliter concepts); the major use of terminal was for teaching computer are according.

Licaentary schools inded greater use of alterocompitters for compensatory, remedial and basic skill, instruction than did senior sith schools, where computer science was the tract prevalent instructional use:

- Almost half (46 percent) of the schools with microcomputers indicated a major need for interocomputer courseware in computer literacy and learning enrichment. Major courseware needs in compensatory ramaginal and tassic skills, instruction were eited by 38 and 37 percent of the schools:
- Publishers were the major source of coursewaire for 26 percent of the schools with interocomputers; followed by vendors (21 percent), the school or district (18 percent); and other educational agencies (12 percent).
- More interocomputers and suitable courseware were perceived as the chief needs for initiating or improving computer-based education by over 50 percent of all schools. Qualified teachers and startup assistance were cited as major needs only slightly less frequently.
- Similar percentages of Title I schools and non-Title I schools (about 35 percent in each case) provided; computer-based instruction to students. Title I authorized grants for elementary and secondary programs for children of low-income families. Non-Title I schools averaged more computers per school (4.7 vs. 3.7), but not; more time of exposure per student (about 9 hours in each case).

# FOREWORD

During the past decade, computers, especially personal microcomputers, have made a great impact on all aspects of American life--business and industry, government, leisure activities, and education. Recently, computers have started to have a major impact in the classroom as increasing numbers of schools have invested in the new technology.

This report presents findings of a national survey conducted by the National Center for Education Statistics (NCES) in spring 1982 to assess recent changes in computer availability and to obtain data about instructional uses and needs from the school perspective. The survey was conducted through the NCES Fast Response Survey System (FRSS), which was established to collect data on emerging educational developments. The preliminary results were first shared with the public in September 1982.

This report is the 14th in the FRSS series and will be useful to public education officials, as well as to concerned individuals and organizations in the private sector.

Marie D. Eldridge Administrator

iii

## ACKNOWLEDGMENTS

This survey was conducted for the Assistant Secretary for Educational Research and Improvement, U.S. Department of Education, in support of the Secretary's technology initiative.

The survey was supported by the Council of Chief State School Officers (CCSSO) through its Committee for Evaluation and information Systems (CEIS). The CEIS Fast Response Panel, chaired by Garth Yeager (Illinois) and composed of Charles Lloyd (Utah), George Malo (Tennessee), Margaret Bingham (North Carolina), and George Rush (CCSSO), offered numerous suggestions that improved the questionnaire.

A number of NCES staff contributed to this survey especially Jeanette Goor and Jean Brandes. The authors acknowledge with gratitude the assistance of the FRSS State Coordinators, who facilitated the data collection, and the respondents who voluntarily provided the data.

The survey was conducted by Westat, Inc., a research firm in Rockville, Maryland, under contract to NCES. The Westat project team included Dianne Walsh, John Burke, Frances Cohen, Lucinda Gray, and Patricia Congdon.

APPENDIX TABLES		,
A.—Number of U.S. public schools in the universe and in the sample; by instructional level, region, and school type		19
B.—Standard errors of selected questionnaire items		21.

Microcomputers first appeared in public school classrooms in the late 1970's. By spring 1982, the number of microcomputers used by students for instruction land grown to almost 100,000—more than triple the number available just 18 months earlier.

This rapid increase in the number of microcomputers in schools is a reflection of the widespread interest by educators, parents, students; and society; generally, in the computer phenomenon.

In 1980, at the request of the Assistant Secretary for the Office of Educational Research and Improvement (OERI), the National Center for Education Statistics (NCES) conducted a survey of school districts on the instructional use of computers by students. One of the earliest national surveys on this topic, the study collected baseline data in support of the Secretary's technology initiative.

In spring 1982, the Assistant Secretary for OERI requested this current survey to provide a better understanding of computer-based education and needs at the school level. The questionnaire, which was sent to a nationally representative sample of public schools, obtained the following information:

Numbers of computers available for all uses (instructional and noninstructional) and for instructional use by students in the 1981-82 school year.

- Number of students using computers for instruction, and the number of computer hours of instructional use in the 1981-82 school year.
- Relative amount of computer time devoted to various instructional purposes.
- Number of teachers trained to teach computer literacy (introduction to computer concepts).
- Number of eredits that students could earn in computer literacy and computer science.
- Needs for and sources of interocomputer courseware (instructional software).
- Needs for initiating or improving computer-based education.

The estimates in this report are based on sample data that have been weighted to produce national estimates. Because these estimates are subject to sampling variability, the numbers in the text have been rounded; however, the numbers in the tables are the actual estimates. Percents have been calculated based on the actual estimates rather than the rounded values.

The methodology for this survey and sumpling errors are discussed in appendix I; the survey questionnaire, which was mailed to the school principal, is presented in appendix II.

Computers were defined in this survey as either small, self-contained personal computers with TV-like screens (microcomputers) or the more traditional computer terminals connected to remote central processors.

#### SURVEY FINDINGS

Computer Availability, in Public Schools in the 4.981\*82 School Year

About two-fifths (38 percent) of the Nation's public schools had one or more computers during the 1981-82 school year (see table 1). Almost all of these schools (93 percent) provided computer-based instruction.

Public schools had access to an estimated, total of 132,000 computer units, of which 91 percent (121,000) were used for instruction. The number of computers available for instruction more than doubled in public schools between fall 1980 (52,000 computers) and spring 1982. Most of the growth occurred in the number of microcomputers (from 31,000 to 96,000), while the number of computer terminals did not change significantly (22,000 vs. 24,000).

School administrators projected a modest growth in the availability of computer-based education for the 1982-83 school year (table 1), but their projections have proved to be too conservative. The these estimates were

made, funds from Chapter 2 of the Education Consolidation and Improvement Act became available to school districts. A recent study by the American Association of School Administrators indicates that many districts are utilizing their Chapter 2 funds to purchase microcomputers for their schools.

The remainder of the report focuses exclusively on computers used for instructional purposes. Tables in the following sections present national estimates for all schools and for schools classified according to instructional level (clementary, junior high, senior high, and combined and other ), secographical region, and metropolitan status (urban, suburban, rural). The final section compares the availability of computer-based instruction in Title I and non-Title I schools. Throughout the report, when averages per school or averages per student are discussed, the reference is with respect to schools offering computer-based instruction.

Becker, Henry, "School Uses of Microcomputers," Center for Social Organization of Schools, Johns Hopkins University, April 1983.

<sup>&</sup>quot;Impact of Chapter 2 of the Education Consolidation and Improvement Act on Local Education Agencies," American Association of School Administrators, March 1983.

Combined and other schools include those with combined elementary and secondary grades, as well as all special education and vocational education schools. The findings for these schools are presented, but are not discussed in the text because this group of schools is relatively small (5,874 out of 81,970 schools) and very diverse.

# Availability of Computer-Based Instruction, by School Characteristics

The 29,000 schools providing computer-based education in 1981-82 possessed 121,000 computers, an average of 4.2 computers per school with computers (table 2). The number of computers available for instruction in individual schools varied greatly; the majority of schools (56 percent) had only one or two units, while 10 percent had 10 or more (not an table).

Both the percent of schools offering computer-based education and the average number of computers per school increased as the instructional level increased. One-fifth (22 percent) of the elementary schools used computers for instruction, compared with 52 percent of the junior high schools and 74 percent of the senior high schools. Elementary schools providing computer-based instruction averaged 2.3 computers per school; while senior highs averaged 6.0. Part of the difference in the number of computers per school may be related to school size as well as instructional level, since secondary schools tend to be larger than elementary schools. example, about three-fifths of senior high schools have enrollments of 500 or more students, compared with 28 percent of the elementary schools.

Regional availability of computer-based education ranged from 27 percent of the schools

in the Southeast region to about 40 percent of the schools in both the North Atlantic region and the Great Lakes and Plains region. The concentration of computers in these schools varied as well—from 2.7 units per school in the Southeast region to 5.8 per school in the West and Southwest region.

Approximately equal proportions of urban, suburban, and rural schools used computers for instruction in 1981-82 (between 33 and 37 percent). However, urban schools with computers averaged more computers per school (6.8) than did suburban (3.9) or rural (3.0) schools.

Administrators in senior high schools also reported the percentage of their graduates who attend college. Schools were classified into three groups: low (25 percent or less), medium (26 to 60 percent), or high (more than 60 percent). Schools with a high percent of graduates attending college were more likely to offer computer-based education (88 percent) than were schools with a low percent of graduates going to\_college (37 percent); about three-fourths (73 percent) of the schools in the middle group had computer-based instruction. The numbers of computers available for instruction ranged from 4.7 in the low group to 7.0 in the high group.

School characteristics	All.	Schools providing computer-based instruction 1		Number of computer units'	. Average number of computer units per school with

Rural	36,133	13,100	37	40,837	3.0

With microcomputers, computer terminals, or both.

Note. -- Numbers may not add to totals because of rounding.

Computer units include both microcomputers and computer terminals.

Based on all schools in each category.

Schools are classified as urban, suburban, or rural based on their ZIP codes. Urban schools have ZIP codes that comprise the central city portion of a standard Metropolitan Statistical Area (SMSA) as defined by the Census Bureau. Suburban schools lie within an SMSA, but outside the central city. Rural schools lie outside SMSA's. Information on metropolitan status was not available for an estimated 1,183 schools. 129 of which provided computer-based education. These schools were excluded from the counts and percentages for metropolitan status:

# Extent of Computer Usage, by School Characteristics

In the 1981-82 school year, 4.7 million public school students (11 percent) received instruction using computers. On the average, each of the 121,000 computers was used for instruction a total of 361 hours during the year (about 2 hours per school day). Each computer was shared by an average of 39 students, and each student in schools with computers averaged 9 hours of computer access in 1981-82 (table 3).

Computer usage varied widely, however, among schools offering computer-based instruction. For example, about 10 percent of the schools used their computers 50 hours or less during 1981-82 (about 17 minutes per day), while 13 percent used their computers 900 hours or more (5 hours per day). Similar variations occurred regarding the length of student exposure to computers. Students in 10 percent of the schools received 1 1/3 hours or less of computer instruction during the 1981-82 school year; at the other end of the scale, students in another 10 percent of schools received 36 hours or more of computer instruction during the year, or 1 hour per week.

It is interesting to note that while proportionately more senior high schools provided computer-based instruction than did elementary schools (table 2), students attending elementary schools that offered computer-based instruction were more likely to receive some exposure to computers than were students attending senior high schools that offered such

instruction (not on table). Although only 9 percent of all elementary school students nationwide received instruction using computers in 1981-82; fully 35 percent of students in elementary schools with computers received such instruction. At the senior high level; however, 15 percent of all students received computer-based instruction, but only 17 percent of students in schools with computers had received the instruction.

Approximately the same number of elementary and senior high school students received computer instruction in 1981-82 (1.7 million students at each level). Further, each computer at the two levels was utilized for instruction about the same amount of time' (400 and 370 hours, for elementary and senior high school computers, respectively). However, as seen in table 2, senior high schools had more than twice as many computer units as elemen-Consequently, the student to tary schools. computer ratio was smaller at the senior high level (28) than at the elementary level (66). Also, senior high school students received a more concentrated exposure to computer-based instruction (13 hours per student in 1981-82), compared with elementary school students (6 hours per student).

The average number of students per computer did not differ significantly by geographical region. The average exposure per student, however, ranged from 7 hours in the Southeast to 12 hours in the Great Lakes and Plains.

### Instructional Uses of Computers

A basic dichotomy exists in the instructional purposes for which computers are put to use in public schools. When used for compensatory/remedial education, teaching basic academic skills, or learning enrichment; the computer is a novel tool that is utilized to accomplish a traditional end. When used to teach computer literacy or computer science; the computer, no longer merely a tool, becomes the subject matter.

Teaching computer literacy was the most prevalent instructional use of microcomputers in public schools, with an estimated 33 percent of all schools with microcomputers devoting a major percentage of total microcomputer time to this purpose (table 4). Nearly two-thirds of the schools with microcomputers (64 percent) reported major or moderate usage for this purpose, and only 15 percent did not offer any instruction in computer literacy.

Twenty-three percent of the schools reported that teaching computer science was a major use of microcomputers; only 16 percent, however, indicated moderate usage of microcomputers for computer science instruction, and 37 percent indicated no computer science instruction. Learning enrichment and basic academic skills instruction were mentioned as major microcomputer uses by 19 percent of the schools; about one-half of the schools made major or moderate usage of their microcomputers for these purposes (54 and 49 percent, respectively).

For schools with terminals, computer science was the most emphasized instructional purpose, with 34 percent of schools reporting major usage. Major usage of terminals for other instructional purposes ranged from 24 percent for learning enrichment to 12 percent for compensatory/remedial instruction.

Computer terminals:  Compensatory/remedial  Basic academic skills  Learning enrichment  Computer literacy  Computer science	12	13	27	47
	13	24	23	40
	24	29	22	25
	22	27	18	32
	34	22	10	34

Percentages for microcomputers are based on an estimated 27,501 schools offering computer-based instruction via microcomputers, while percentages for terminals are based on 5,898 schools with computer terminals. Of the estimated 29,028 schools offering computer-based instruction with either microcomputers or terminals or both, 23,130 have microcomputers only, 1,527 have terminals only, and 4,371 have both microcomputers and terminals.

Note: -- Row percents may not add to 100 because of rounding.

# Instructional Uses of Computers, by School Characteristics

The major allocation of microcomputer time for instruction varied by instructional level. In elementary and junior high schools, computer literacy was more frequently a major instructional use of microcomputers than was computer science; in senior high schools, the pattern was reversed (table 5). Nearly half (49 percent) of senior high schools allocated a major amount of microcomputer time for instruction in computer science, while 39 percent did so for computer literacy. Microcomputers were used more often as a tool to teach traditional subjects in elementary schools than in senior high schools. They were used heavily to teach basic academic skills in 29 percent of elementary schools, compared with only 12 percent of senior high schools.

Computer literacy was the most prevalent major instructional purpose of microcomputers in the North Atlantic (30 percent) and Great Lakes and Plains (31 percent), as well as in suburban areas (37 percent) and rural areas (31 percent).

Most of the observed differences in terminal usage by school characteristics were not significant because the sample number of schools with terminals was small. For example, although major terminal use for computer literacy and learning enrichment in urban schools differed by 17 percent based on this sample, the difference was not statistically significant.

Table 5:--Major allocation of computer time for instruction, by type of computer unit and school characteristics: United States, spring 1982

Respondents could indicate zero, one, or more than one major instructional purpose:

Information on metropolitan status was not available for an estimated 129 schools providing computer-based education (excluded from this analysis).

# Computer Literacy and Computer Science

In addition to providing information on the relative amount of computer time devoted to computer literacy and computer science, school administrators supplied information on the number of credits that students could earn in these subjects (if applicable) and on the number of teachers who were highly, moderately, or minimally qualified to teach computer literacy.

Over four-fifths of the senior high schools with computers offered some instruction in computer literacy (88 percent) or computer science (85 percent) using either microcomputers or computer terminals. According to administrators, credit courses were available in 58 percent of the senior high schools offering computer literacy; on the average, students in these schools could earn 1.9 credits in computer literacy. Three-fourths of the senior highs with computer science instruction offered credit courses in the subject; on the average, 2.4 credits could be earned.

Despite the widespread availability of computer literacy instruction in schools with computers, there were relatively few teachers who were highly trained to teach computer literacy. Administrators estimated that 37,000 teachers were highly qualified to teach computer literacy, an average of 1.3 teachers per school with computers (table 6). However, 44 percent of the schools with computers had no teachers who were highly qualified, while a small fraction (4 percent) had 5 or more. Moderately and minimally qualified teachers in 1981-82 numbered 55,000 and 122,000; per school averages were 1.9 and 4.2, respectively.

By school characteristics, the numbers of highly trained teachers ranged from .7 teachers per school in combined and other schools with computers to 1.6 per senior high school and schools in the North Atlantic.

Table 6.--Average number of teachers per school with computers for instruction who are qualified to teach computer literacy; by school characteristics: United States, spring 1982

Information on metropolitan status was not available for an estimated 129 schools providing computer-based education (excluded from this analysis).

# Needs for Microcomputer Courseware

The leading courseware needs were in the fields of computer literacy and learning enrichment; each was reported as a major need by 46 percent of the schools with microcomputers (table 7). Courseware for compensatory/remedial and basic skills instruction were regarded as major needs by 38 and 37 percent, respectively, of the school administrators. When ratings of moderate need were included, courseware needs ranged from 77 percent for compensatory/remedial instruction to 90 percent for learning enrichment.

At the elementary level, software needs for compensatory/remedial and basic skills instruction were similar to those for learning enrichment and computer literacy. Adminis-

trators in senior highs, however, regarded computer literacy courseware as a greater need than courseware for either basic skills or compensatory/remedial instruction.

Some regional differences emerged in the need for microcomputer software. For example, only about one-fourth of the North Atlantic schools reported a major need for basic skills courseware, compared with almost half of the schools in both the Southeast and West and Southwest. Administrators in schools in the Southeast also perceived the need for learning enrichment courseware more strongly than administrators in the Great Lakes and Plains region.

Respondents could indicate zero, one, or more than one major courseware need.

21

Information on metropolitan status was not available for an estimated 129 schools providing computer=based education (excluded from this analysis).

# Sources of Microcomputer Courseware

About one-fourth of the schools with microcomputers obtained all or most of their software from publishers (table 8). Vendors were the chief sources of courseware for 21 percent of the schools, and 18 percent relied mainly on courseware developed within the school or district. Other education agencies were the least frequent of the four listed sources of software.

With a few exceptions, chief courseware sources did not differ by the instructional level or metropolitan status of schools; they did differ, however, by geographical region. Almost one-fourth of the schools in the Great Lakes and Plains region reported that other education agencies supplied all or most of their software. In the other regions, other education agencies

were a major software source for only 4 to 9 percent of the schools with microcomputers. This difference probably reflects the impact of computing consortia, such as the Minnesota Educational Computing Consortium (MECC), which has been developing and disseminating instructional software in the Midwest for 10 years.

Differences in the utilization of course-ware sources also occurred within regions. For example, Great Lakes and Plains schools with microcomputers obtained courseware significantly more often from publishers than from vendors. For schools in the West and Southwest, however, vendors were the most frequent major supplier of courseware.

Needs for Initiating or Improving Computer-Based-Education

According to school administrators, more microcomputers and suitable courseware are the chief needs for initiating or improving computer-based education. Over 60 percent of all administrators rated these needs as having major importance (table 9). About half of the administrators regarded qualified teachers and startup assistance as major needs, while 41 percent cited staff/community support.

Major needs of schools already providing computer-based education differed from those of schools without computers. Administrators in schools with computers were more-likely to stress the need for more microcomputers and suitable courseware compared with administrators in schools without computers. On the other hand, proportionately more schools without computers cited startup assistance, qualified

teachers, and staff/community support as major needs.

Some of the differences of needs by instructional level reflected the differences in availability of computer-based education by instructional level. For instance, compared with elementary schools, senior highs were less likely to rate startup assistance as a major need and more likely to regard more microcomputers as critical. In fact, administrators in senior high schools viewed the need for more microcomputers as even more important than the need for courseware.

Ratings of needs by geographical region and by metropolitan status generally showed the same pattern as national ratings.

Respondents could indicate zero; one; or more than one major need for improving computer-based education:

Information on metropolitan status was not available for an estimated 1,183 schools (excluded from this analysis).

# Computer-Based Education in Title I and Non-Title I Schools

School administrators also indicated whether their school received Title I assistance. Title I authorized grants for elementary and secondary school programs for children of lowincome families. Table 10 compares the availability of computer-based education, usage, and needs in Title I and non-Title I schools. Similar percentages of Title I and non-Title I schools-35 percent of all Title I schools and 36 percent of non-Title I schools—had computers available for instruction in 1981-82. Although non-Title I schools averaged more computers per school than Title I schools (4.7 vs. 3.7), no significant differences occurred for students per computer (42.6 vs. 35.7) or hours of exposure per student (9.2 vs. 9.3).

Differences did show up in the uses of microcomputers. Title I schools were more likely to allocate a major portion of their microcomputer time for compensatory/remedial education (19 percent vs. 9 percent) than were non-Title I schools. Title I schools also were

more likely to indicate a major need for course-ware for this instructional purpose. Non-Title I schools emphasized teaching computer literacy and computer science to a greater extent than Title I schools did. Two out of five non-Title I schools spent a major portion of their micro-computer time on computer literacy, compared with only one-fourth of the Title I schools. The size of difference was similar for computer science: 31 percent of non-Title I schools versus 16 percent of Title I schools allocated a major portion of their total microcomputer time to this purpose.

Regarding major needs for initiating dr improving computer-based education in their schools, Title I and non-Title I schools differed only in the extent to which they viewed the need for more microcomputers. Administrators in 68 percent of the non-Title I schools regarded obtaining more microcomputers as a major need, compared with 60 percent of the administrators in Title I schools.

# The Fast Response Survey System

The Fast Response Survey System (FRSS) was established by NCES so that education data, urgently needed for planning and policy formulation, could be collected quickly and with minimum burden on respondents.

The PRSS covers six education sectors:

State Education agencies (SEA's). Local education agencies (LEA's)
Public elementary and secondary schools
Private elementary and secondary schools
Institutions of higher education
Noncollegiate postsecondary schools with occupational programs.

All 50 States and the District of Columbia are included in the SEA sector. For each of the other sectors, in stratified random sample was designed to allow yalld national estimates to be made. The sample sizes range from 500 to 1,000.

A data-collection network involving both respondents and coordinators was developed in each sector. Coordinators assist in the data collection by maintaining liaison with the sampled institutions or agencies. The respondents, selected to report for their institutions or agencies, voluntarily provide the policy-oriented data requested in the questionnaires.

The FRSS provides NCES with a mechanism for furnishing data quickly and efficiently. All aspects of the system—the sample design, the network of coordinators and respondents, and the short questionnaires—have been designed with this end in mind.

Methodology for the Survey of Instructional Use of Computers in Public Schools

This study was based on a stratified national sample of 900 public schools. The universe used to select the sample was a file of approximately 82,300 public school buildings compiled in October 1981 by Market Data Retrieval, Inc. (Westport, Connecticut). In order to increase efficiency, schools identified on the file as having microcomputers were sampled separately and at a higher rate than the remaining schools. Additional stratification was based on instructional level, building enrollment, geographical region, district enrollment, and metropolitan status.

After adjusting for school closings and out-of-scope selections, the number of potential respondents was 896, representing a total of 81,970 public schools. Questionnaires were mailed to these respondents in April 1982. Data collection by mail and telephone continued until a 92 percent response (825 questionnaires) was obtained.

The response data were weighted to produce national estimates, and a weight adjustment was made to account for survey nonresponse. The adjustments were calculated for each cell of a three-way tabulation of microcomputer indicator by instructional level by region. Table A shows the cell totals used in the weighting. The data were not adjusted for item, nonresponse, which was quite small (ranging from less than 1 percent to 2.4 percent).

<sup>\*</sup>Adjusted down from 1,348 to account for two school closings.

<sup>\*\*</sup>Adjusted down from 1.271 to account for two out-of-scope units.

The source of the universe tile was Market Data Retrieval/CIC Data Base, fall 1981. In compiling data base, MDR identified each school either as having a microcomputer for instruction or not

# Standard Errors of the Statistics

The findings presented in this report are estimates based on the FRSS sample of public schools and, consequently, are subject to sampling variability. If the questionnaire had been sent to a different sample, the responses would not have been identical; some estimates might have been higher, while others might have been lower. The estimated standard error of a statistic (a measure of the variation due to sampling) can be used to examine the precision obtained in a particular sample. If all possible samples were surveyed under similar conditions, intervals of 1.645 standard errors below to 1.645 standard errors above a particular statistic would include the average result of these samples in approximately 90 percent of the eases. For example, for the number of computers available for instruction (table B), the 90

percent confidence interval is from 107,355 to 134,461 computers (120,908 + 1.645 times a standard error of 8,239). If the above procedure were followed for every possible sample, about 90, percent of the intervals would include the average number from all possible samples.

Table B presents standard errors (calculated by balanced repeated replication) for selected questionnaire items. Specific statements of comparison in the text are significant at least at the 80 percent confidence level, and most are significant at the 90 percent level. Standard errors for other questionnaire items and statistics presented in this report, not included in table B, can be obtained on request.
